

Python basics

- Comments
- `”.”`
;
- Variable names
- `int, float, str`
- type conversion
- assignment (`=`)
- `print(), help(), type()`

Python comments

A '#' indicates the beginning of a comment. From '#' until the end of line is ignored by Python.

```
x = 42 # and here goes the comment
```

Comments useful to describe what a piece of code is supposed to do, what kind of input is expected, what is the output, side effects...

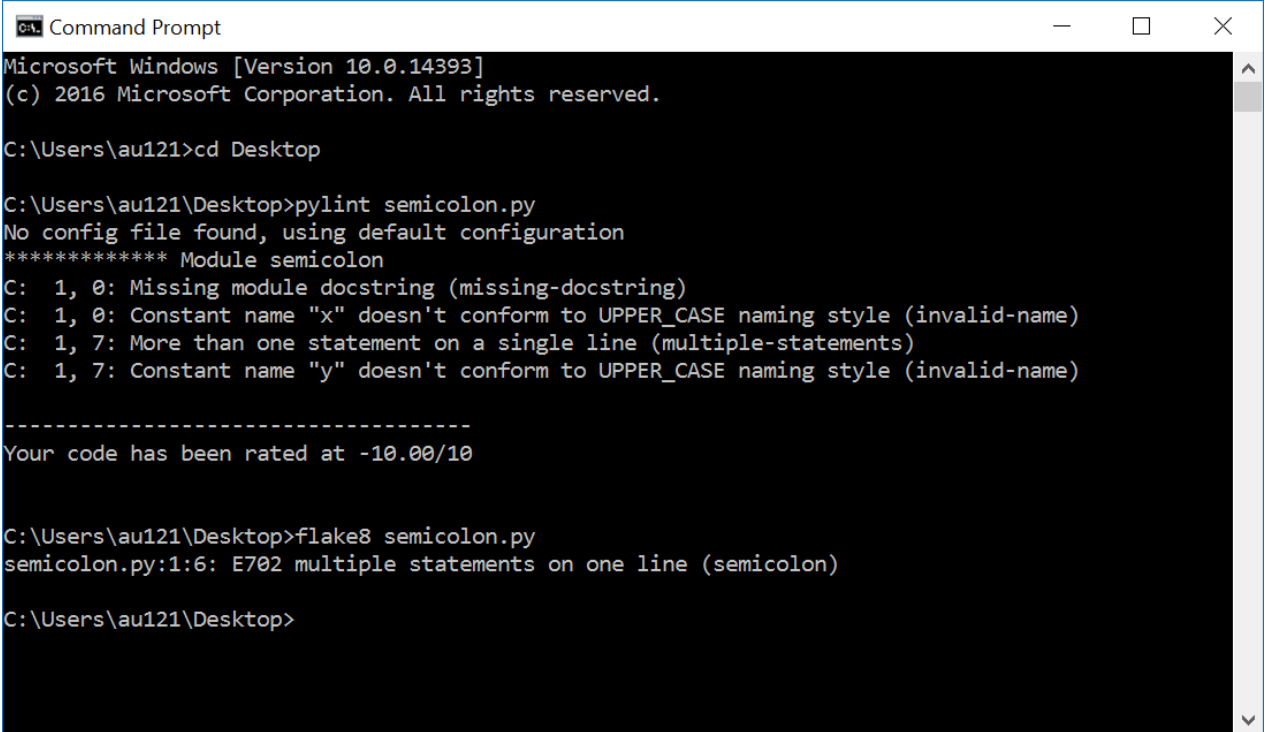

The “;” in Python

- Normally statements follow in consecutive lines with identical indentation

```
x = 1
y = 1
```

- but Python also allows multiple statements on one line, separated by “;”

```
x = 1; y = 1
```

```
Command Prompt

C:\Users\au121>cd Desktop

C:\Users\au121\Desktop>pylint semicolon.py
No config file found, using default configuration
***** Module semicolon
C:  1, 0: Missing module docstring (missing-docstring)
C:  1, 0: Constant name "x" doesn't conform to UPPER_CASE naming style (invalid-name)
C:  1, 7: More than one statement on a single line (multiple-statements)
C:  1, 7: Constant name "y" doesn't conform to UPPER_CASE naming style (invalid-name)

-----
Your code has been rated at -10.00/10

C:\Users\au121\Desktop>flake8 semicolon.py
semicolon.py:1:6: E702 multiple statements on one line (semicolon)

C:\Users\au121\Desktop>
```

neither **pylint** or **flake8** like “;”

- General Python guideline: **avoid using “;”**
- Other languages like C, C++ and Java require “;” to end/separate statements

Variable names

- Variable name = sequence of **letters** 'a'-'z', 'A'-'Z', **digits** '0'-'9', and **underscore** '_'

v, volume, height_of_box, WidthOfBox, x0, _v12_34B, _
(snake_case) (CamelCase)

- a name cannot start with a digit
 - names are case sensitive (AB, Ab, aB and ab are different variables)
- Variable names are **references to objects in memory**
 - **Use meaningful variables names**
 - **Python 3 reserved keywords:** and, as, assert, break, class, continue, def, del, elif, else, except, False, finally, for, from, global, if, import, in, is, lambda, nonlocal, None, not, or pass, raise, return, True, try, while, with, yield

Question – Not a valid Python variable name?

- a) `print`
-  b) `for` ← Python reserved keyword
- c) `_100`
- d) `x`
- e) `_`
- f) `python_for_ever`
- g) Don't know

```
Python shell
> print = 7
> print(42)
| Traceback (most recent call last):
|   File "<stdin>", line 1, in <module>
| TypeError: 'int' object is not callable
```

`print` is a valid variable name, with default value a builtin *function* to print output to a shell – assigning a new value to `print` is very likely a bad idea

Integer literals

- -4, -3, -2, -1, 0, 1, 2, 3, 4
- Python integers can have an arbitrary number of digits (only limited by machine memory)
- Can be preceded by a plus (+) or minus (-)
- For readability underscores (_) can be added between digits,

2_147_483_647

(for more, see [PEP 515 - Underscores in Numeric Literals](#))

Question – What statement will not fail?

a) $x = _42$

b) $_10 = -1_1$

c) $x = 1__0$

d) $x = +1_0__$

e) Don't know

Float literals

- Decimal numbers are represented using **float** – contain “.” or “e”
-  Floats are often only approximations, e.g. `0.1` is not $1/10$
- Extreme values (CPython 3.6.4)
 - `max = 1.7976931348623157e+308`
 - `min = 2.2250738585072014e-308`
- Examples
 - `3.1415`
 - `-.00134`
 - `124e3 = 124 · 103`
 - `-2.345e2 = -234.5`
 - `12.3e-4 = 0.00123`

Associativity rule does not apply to floats

Python shell

```
> 0.1+0.2+0.3
| 0.600000000000000001
> (0.1+0.2)+0.3
| 0.600000000000000001
> 0.1+(0.2+0.3)
| 0.6
> 0.1+(0.2+0.3) == (0.1+0.2)+0.3
| False
> type(0.1)
| <class 'float'>
> 1e200*1e300
| inf
```

Question – What addition order is “best”?

a) $1e10 + 1e-10 + -5e-12 + -1e10$

b) $1e10 + -1e10 + 1e-10 + -5e-12$

c) $1e-10 + 1e10 + -1e10 + -5e-12$

d) $-5e-12 + -1e10 + 1e10 + 1e-10$

e) Any order is equally good

f) Don't know

$1e10$	=	10000000000
$-1e10$	=	-10000000000
$1e-10$	=	0.0000000001
$-5e-12$	=	-0.000000000005

```
Python shell
> 1e10 + 1e-10 + -5e-12 + -1e10
| 0.0
> 1e10 + -1e10 + 1e-10 + -5e-12
| 9.5000000000000001e-11
> 1e-10 + 1e10 + -1e10 + -5e-12
| -5e-12
> -5e-12 + -1e10 + 1e10 + 1e-10
| 1e-10
```

a) - d) give four different outputs

Approximating $\pi = 3.14159265359\dots$

$$\frac{\pi^2}{6} = \sum_{k=1}^{+\infty} \frac{1}{k^2} = 1.6449340668\dots$$

Riemann zeta function $\zeta(2)$

```
pi_approximation_riemann.py
```

```
apx = 0.0
k = 0.0
while True:
    k = k + 1.0
    apx = apx + 1.0 / (k*k)
    print(k, apx)
```

Output

```
...
94906261.0 1.6449340578345741
94906262.0 1.6449340578345744
94906263.0 1.6449340578345746
94906264.0 1.6449340578345748
94906265.0 1.644934057834575
94906266.0 1.644934057834575
94906267.0 1.644934057834575
94906268.0 1.644934057834575
94906269.0 1.644934057834575
94906270.0 1.644934057834575
...
```

This is not a course in numeric computations – but now you are warned....

Question – What does the following print ?

```
print ("\\\\" "\n\n")
```

- a) \\\"\\n\n'
- b) \"\nn'
-  c) \"\n
'
- d) \"nn'
- e) \"
'
- f) Don't know

print(...)

- `print` can print zero, one, or more values
- default behavior
 - print a space between values
 - print a line break after printing all values
- default behavior can be changed by **keyword arguments** “`sep`” and “`end`”

Python shell

```
> print()
|
> print(7)
| 7
> print(2, 'Hello')
| 2 Hello
> print(3, 'a', 4)
| 3 a 4
> print(3, 'a', 4, sep=':')
| 3:a:4
> print(5); print(6)
| 5
| 6
> print(5, end=', '); print(6)
| 5, 6
```

print(...) and help(...)

Python shell

```
> help(print)
```

```
| Help on built-in function print in module builtins:
```

```
| print(...)
```

```
|     print(value, ..., sep=' ', end='\n', file=sys.stdout, flush=False)
```

```
|     Prints the values to a stream, or to sys.stdout by default.
```

```
|     Optional keyword arguments:
```

```
|     file: a file-like object (stream); defaults to the current sys.stdout.
```

```
|     sep: string inserted between values, default a space.
```

```
|     end: string appended after the last value, default a newline.
```

```
|     flush: whether to forcibly flush the stream.
```

Assignments

- *variable = expression*

$x = 42$

- Multiple assignments – right hand side evaluated before assignment

$x, y, z = 2, 5, 7$

- Useful for swapping

$x, y = y, x$

- Assigning multiple variables same value in left-to-right

$x = y = z = 7$

Warning

```
i = 1
```

```
i = v[i] = 3 # v[3] is assigned value 3
```

In languages like C and C++ instead
v[1] is assigned 3

Python is dynamically typed, type(...)

- The current type of a value can be inspected using the **type()** function (that returns a type object)
- In Python the values contained in a variable over time can be of different type
- In languages like C, C++ and Java variables are declared with a given type, e.g.

```
int x = 42;
```

and the different values stored in this variable must remain of this type

Python shell

```
> x = 1
> type(x)
| <class 'int'>
> x = 'Hello'
> type(x)
| <class 'str'>
> type(42)
| <class 'int'>
> type(type(42))
| <class 'type'>
```

x new type

Type conversion

- Convert a value to another type:

new-type(value)

- Sometimes done automatically:

`1.0+7=1.0+float(7)=8.0`

Python shell

```
> float(42)
| 42.0
> int(7.8)
| 7
> x = 7
> print("x = " + x)
| Traceback (most recent call last):
|   File "<stdin>", line 1, in <module>
| TypeError: must be str, not int
> print("x = " + str(x))
| x = 7
> print("x = " + str(float(x)))
| x = 7.0
> int("7.3")
| Traceback (most recent call last):
|   File "<stdin>", line 1, in <module>
| ValueError: invalid literal for int() with base 10: '7.3'
> int(float("7.3"))
| 7
```

Questions – `str(float(int(float("7.5"))))` ?

a) 7

b) 7.0

c) 7.5

d) "7"

e) "7.0"

f) "7.5"

g) Don't know
