Range Queries in One Dimension

Preprocess a set S of n elements from a totally ordered universe U to support online range queries

Member(a) $a \in S$?

Pred(a) $\max\{x \in S \mid x \leq a\}$ or \perp

FindAny(a, b) any $e \in S \cap [a, b]$ or \perp

Report(a, b) $S \cap [a, b]$

Count(a, b) $|S \cap [a, b]|$

Count $_{\varepsilon}$ (a, b) $\text{Count}(a, b) \leq \text{Count}_{\varepsilon}(a, b) \leq (1 + \varepsilon) \cdot \text{Count}(a, b)$

Fact Comparison based all queries require time $\Omega(\log n)$

RAM Model

Unit cost RAM with **word size** w , $U = \{0, 1, \dots, 2^w - 1\}$

Instructions: $+$, $*$, \neg , \vee , shifting, random bits, ...

Theorem

Supporting Member requires space $\Omega(n)$ words, for $n \leq 2^{(1-\epsilon)w}$

Theorem

Member, Pred, FindAny, Count, Count $_{\epsilon}$ in **constant time** and
 Report in **time** $O(1 + |\text{output}|)$ using space $O(2^w)$ words

† “FKS”

* Optimal query time

Our Result

	Query time	Space
FindAny	1	n
Report	$1 + \text{output} $	n
Count _{ϵ}	$\log \frac{1}{\epsilon}$	n

Preprocessing expected time $O(n\sqrt{w})$

The Basic Idea

$\text{FindAny}(a, b) \in [a, b] \cap \{\text{lca}(a, b).\text{left.max}, \text{lca}(a, b).\text{right.min}\}$

where

$$\text{lca}(a, b) = (2^{w-1} + \lfloor a/2 \rfloor) \downarrow \text{msb}(a \oplus b)$$

Lemma

FKS on \bullet nodes \Rightarrow space $O(n \cdot w)$ words and FindAny constant time

The Second Idea

v is the nearest ancestor of $\text{lca}(a, b)$ where both subtrees are nonempty

$$\text{FindAny}(a, b) \in [a, b] \cap \{v.\text{left}.\{\text{min}, \text{max}\}, v.\text{right}.\{\text{min}, \text{max}\}\}$$

Lemma

Store \bullet nodes, and $\text{depth}(v) - \text{depth}(\text{lca}(a, b))$ for all $\text{lca}(a, b)$ with nonempty subtrees ($\leq nw$ nodes) using a perfect hash function [Schmidt, Siegel 1990] \Rightarrow space $O(n + \frac{n \cdot w \cdot \log w}{w}) = O(n \log w)$

The Last Idea

Lemma

Only store a subset of $\text{depth}(v) - \text{depth}(\text{lca}(a, b))$ (● nodes)
 [Schmidt, Siegel 1990] \Rightarrow space $O\left(n + \frac{n \cdot \sqrt{w} \cdot \log w}{w}\right) = O(n)$

Theorem

FindAny can be supported in constant time and space $O(n)$

Approximate Range Counting

Partition elements into **blocks** of size $\log n$

For each block keep two **Q-heaps** [Fredman, Willard, 1994]

- **Linear space**
- **Rank** queries in **constant time** (for logarithmic sized problems)
- One Q-heap for the $O(\log n)$ elements in the block
- One Q-heap for the $1, 2, \dots, 2^i, \dots$ neighbors

Theorem Count_ε can be supported in **time** $O(\log \frac{1}{\varepsilon})$ and **space** $O(n)$

Note ε is not used in the preprocessing

Summary

	Query time	Space
FindAny	1	n
Report	$1 + \text{output} $	n
Count _{ϵ}	$\log \frac{1}{\epsilon}$	n

Preprocessing expected time $O(n\sqrt{w})$

FindAny

```
Proc FindAny( $a, b$ )  
  if  $a \leq b$  then  
     $H = 1 \uparrow (\text{msb}(w) \downarrow 1)$   
     $d = \text{msb}(a \oplus b)$   
     $u = ((1 \uparrow (w - 1)) + (a \downarrow 1)) \downarrow d$   
     $z = u \downarrow ((w - 1 - d) \wedge (H - 1))$   
     $v = B[z] ? V[u \downarrow D[u]] : V[z \downarrow D[z]]$   
    for  $x \in \{v.\text{left}.m, v.\text{left}.M, v.\text{right}.m, v.\text{right}.M\}$   
      if  $x \in [a, b]$  then return  $x$   
  return  $\perp$ 
```
